【2024 Advanced Computer Networks Homework 3】

Rules

1. 請在 Ubuntu 24.04 下完成本次作業。
2. 請使用 C 語言(不接受 Python) 完成本次作業，並請提供 Makefile 來編譯你的程式。
3. 禁止抄襲任何人的作業。
4. 請將作業壓縮成 zip 或 tar 檔案，命名為 TCPIP_HW3.zip，並於期限內上傳至中山網路大學 (http://cu.nsysu.edu.tw/)。
5. 如果未遵守上述規則，作業以 0 分計算。
6. TAs email: net_ta@net.nsysu.edu.tw
7. Lab: Network & System Laboratory - EC5018 (11:00~17:00)
8. Deadline: 電子檔請於 2024/10/23 9:10 前上傳至網路大學。

Rules:

1. Please finish this assignment under Ubuntu 24.04 OS system.
2. Please use C language (Python is not accepted) to complete this assignment, and please provide a Makefile to compile your program.
3. Plagiarism of anyone's work is prohibited.
4. Compress this assignment to a zip file, and name it "TCPIP_HW3.zip" and submit it to the Cyber University system before the deadline.
5. If the above rules are not followed, the assignment will be graded as 0 points.
6. If you have any question, please send email to net_ta@net.nsysu.edu.tw or drop by Room EC5018 from 11 to 5 o'clock. However, TA will not help you to debug program.

Deadline: Submit your file to the Cyber University system before 2024/10/23 09:10

Hint

It is important:

1. structure of arp_packet in “arp.h” .
2. ioctl() and structure of ifreq.
3. htons() and ntohs().
4. Wireshark can help you know what the packet fields are.

Motivation

To learn how to build, send and receive Ethernet frames. You will know how ARP works by this homework.

Part 1

The purpose of the attached program *main.c* is to capture ARP packets. You are asked to complete this program. *arp.h* is included to refer ARP packet format in main.

Request

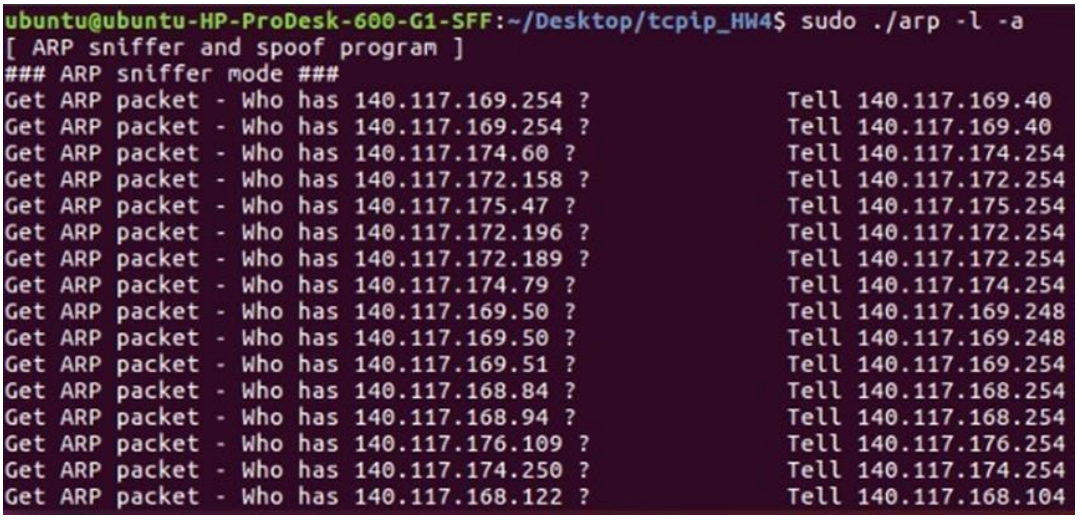
Show usage when the command with insufficient or excessive parameters. You need to validate IP and MAC address format. This program is executed with superuser privilege. Without the superuser right, an error message must be illustrated.

```
ubuntu@ubuntu-HP-ProDesk-600-G1-SFF:~/Desktop/tcpip_HW4$ ./arp
ERROR: You must be root to use this tool!
```

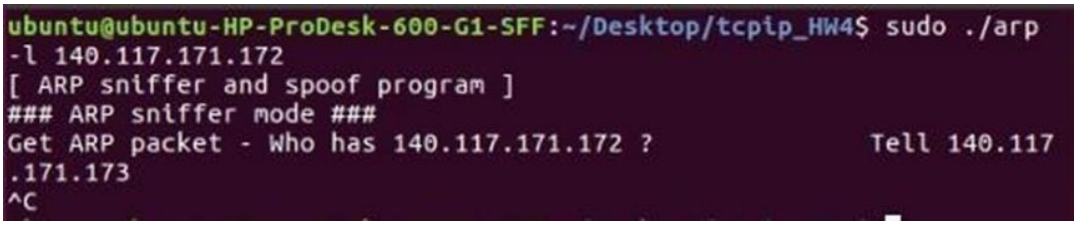
Use ./arp -help to show the detail of the option of the command.

```
ubuntu@ubuntu-HP-ProDesk-600-G1-SFF:~/Desktop/tcpip_HW4$ sudo ./arp -help
[ ARP sniffer and spoof program ]
Format :
1) ./arp -l -a
2) ./arp -l <filter_ip_address>
3) ./arp -q <query_ip_address>
4) ./arp <fake_mac_address> <taget_ip_address>
```

Use ./arp -l -a command to show all of the ARP packets.



Use ./arp -l <ip address> command to implement a filter to capture specific ARP packets.

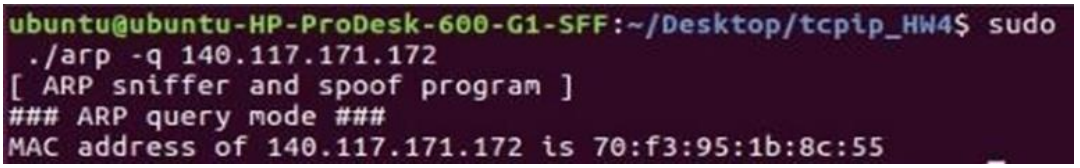


Part 2

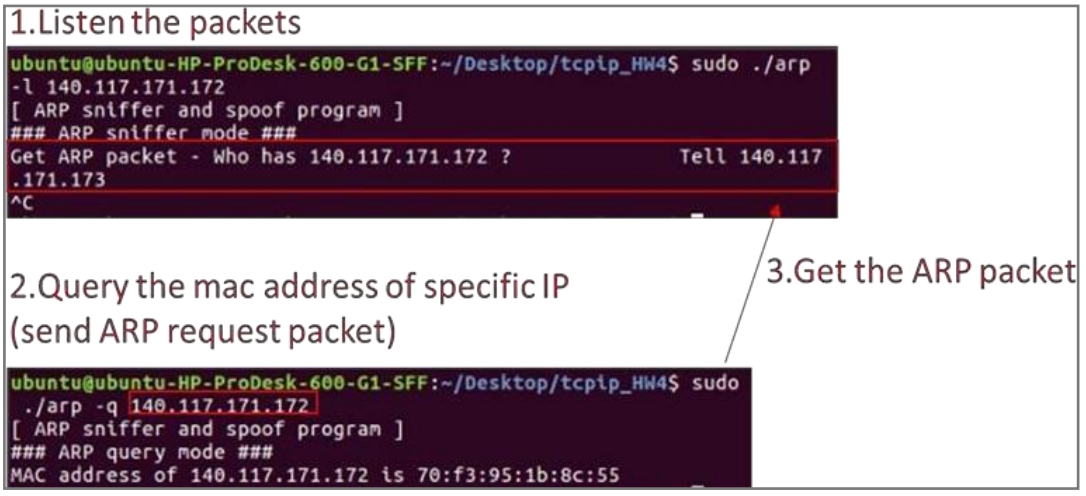
Send an ARP request and receive the ARP reply to find the MAC address of a specific IP. In general, we find the MAC address by cleaning the ARP cache, pinging a specific IP, capturing the packets with something like Wireshark and analyze the packet by yourself. In this part, you implement it to do the same thing.

Request

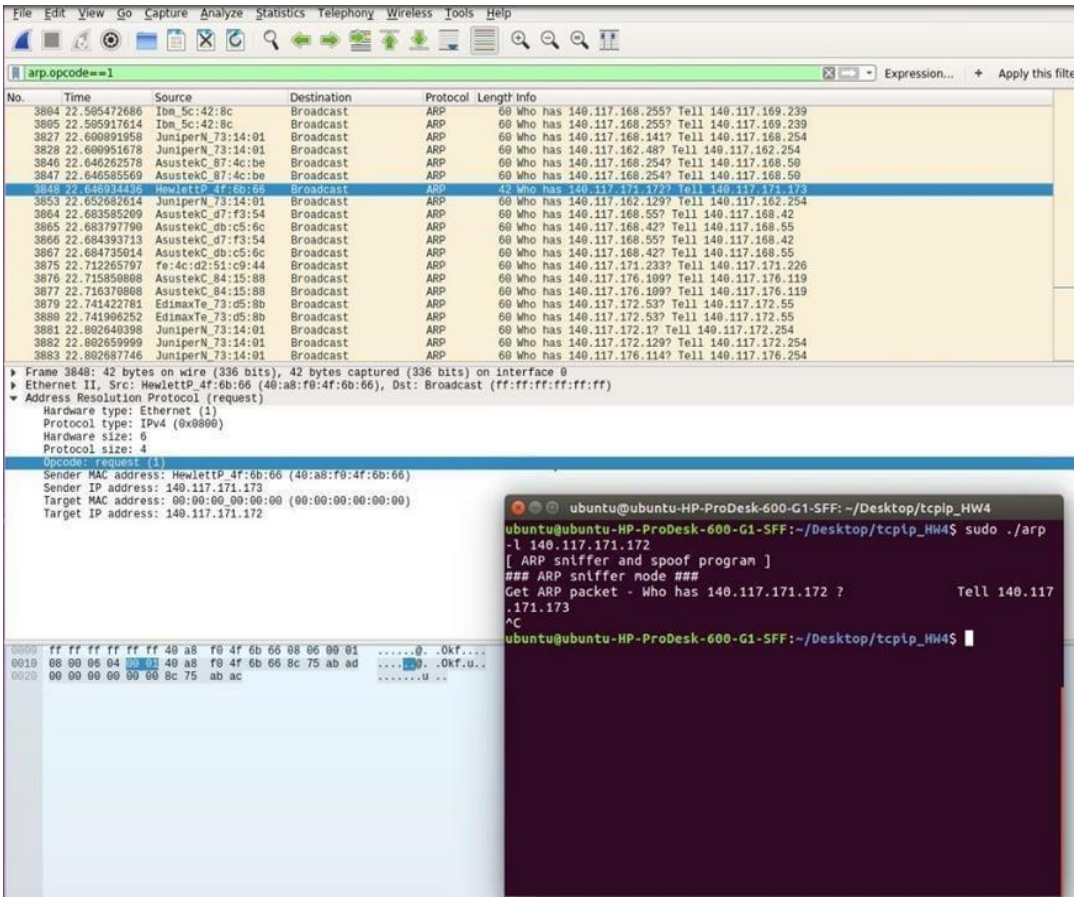
Fill an ARP request packet and send it by broadcast to query the MAC address of a specific IP address.



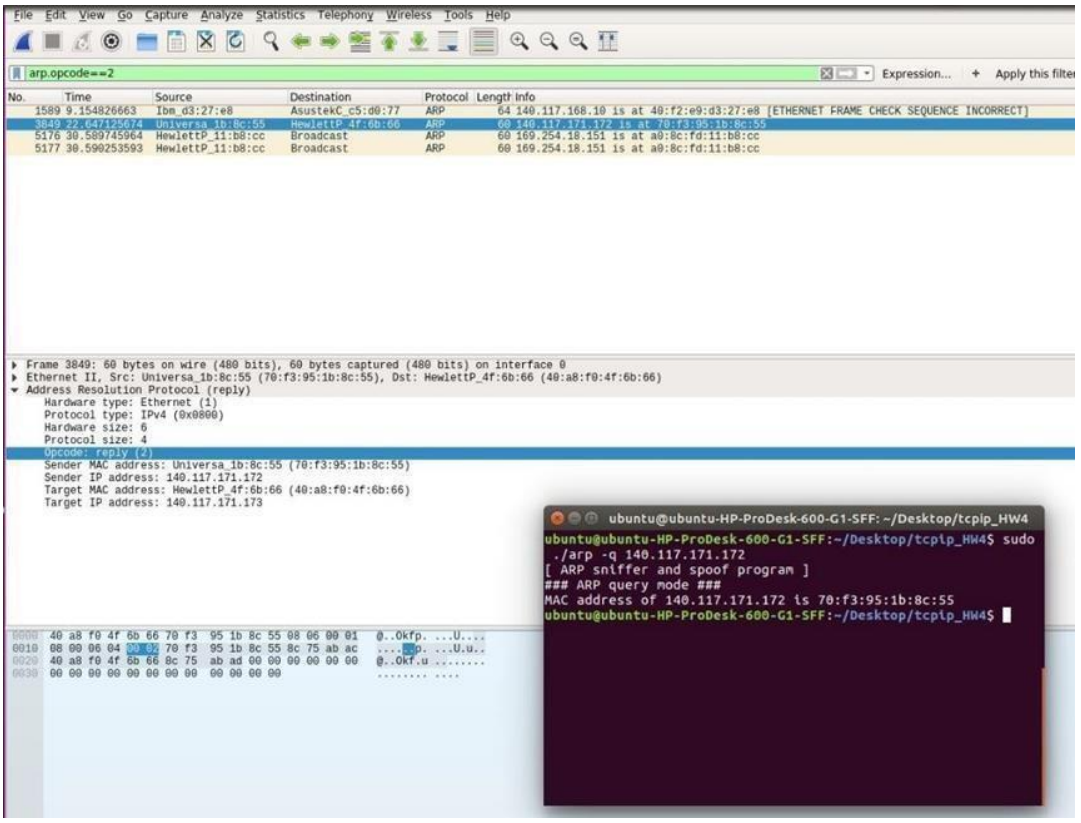
If the IP is offline, you might not find its MAC address, so you must check the network connection before your program executed. You can use **ifconfig** on Linux or **ipconfig /all** on Windows to get the MAC address of a computer. Also, you can use Wireshark to verify your ARP packets sent and received. The ARP filter in the part 1 can be applied to confirm whether the request packet sent in part 2 is successfully or not.



Verify the request packets you send.



Verify the reply packets you receive.

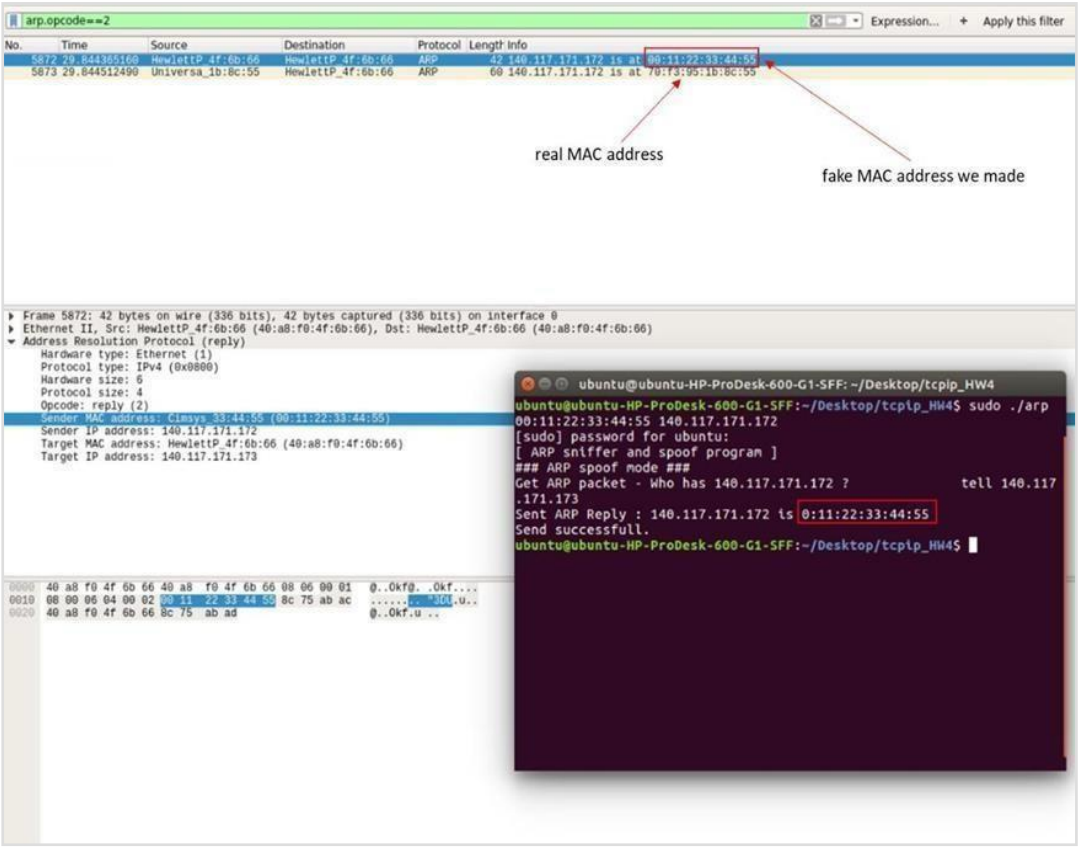


Part 3

Make an ARP daemon, it can reply a MAC address when it receivesspecific IP address.

Request

When the program receives an ARP request for 140.117.171.172, for example, send a 00:11:22:33:44:55 reply. (NOTE: Please DO NOT use the same IP (140.117.171.172) to test your homework when you are doing part 3. It is just an example.)



You can use another computer and ping 140.117.171.172, it will send an ARP request packet. Your program will send an ARP reply at the same time. (If it does not work, you may clear your ARP cache first.) You can use Wireshark to capture the packet you made. There have two ARP packets, one is from true target (70:f3:95:1b:8c:55), another is fake (00:11:22:33:44:55).

Notice

1. In the Part 2 and Part 3, TAs will use Wireshark to verify the ARP reply you made, so make sure your ARP format is as same as the above picture.
2. The packets you send should completely follow the ARP standard packet format, every field should be correct and not be empty.

The above example is not correct, because of missing target IP address.

3. ARP spoofing is illegal! Do not attack the others' devices!
4. You should build an ARP spoofing target of **yours**. For the above example, spoofing target is 140.117.171.172.
5. This homework requires superuser privileges, so you shouldbuildyour own Ubuntu Linux 22.04 host for this homework. We will not provide server's superuser privileges to you.
6. Make sure your program to be working correctly in the following ***arp*** command usage format:

   ./arp –help

   ./arp –l –a

   ./arp –l <filter_ip_address>

   ./arp –q <query_ip_address >

   ./arp <fake_mac_address> <target_ip_address>
